July 2012, Barcelona, Spain.

\*Supported by MCYT's grant DPI2011-25822 and SGR program.

We study the *set of periods* of the 2-periodic Lyness' equations

$$u_{n+2} = \frac{a_n + u_{n+1}}{u_n}, \quad (1)$$

where

$$a_n = \begin{cases} a & \text{for } n = 2\ell + 1, \\ b & \text{for } n = 2\ell, \end{cases} \quad (2)$$

and being  $(u_1, u_2) \in \mathcal{Q}^+$ ;  $\ell \in \mathbb{N}$  and  $a > 0, b > 0$ .

This can be done using the *composition map*:

$$F_{b,a}(x, y) := (F_b \circ F_a)(x, y) = \left( \frac{a+y}{x}, \frac{a+bx+y}{xy} \right), \quad (3)$$

where  $F_a$  and  $F_b$  are the Lyness maps:  $F_\alpha(x, y) = \left( y, \frac{\alpha+y}{x} \right)$ . Indeed:

$$(u_1, u_2) \xrightarrow{F_a} (u_2, u_3) \xrightarrow{F_b} (u_3, u_4) \xrightarrow{F_a} (u_4, u_5) \xrightarrow{F_b} (u_5, u_6) \xrightarrow{F_a} \dots$$

## The map $F_{b,a}$ :

- Is a **QRT** map whose first integral is (Quispel, Roberts, Thompson; 1989):

$$V_{b,a}(x, y) = \frac{(bx+a)(ay+b)(ax+by+ab)}{xy},$$

see also (Janowski, Kulenović, Nurkanović; 2007) and (Feuer, Janowski, Ladas; 1996).

- Has a **unique** fixed point  $(x_c, y_c) \in \mathcal{Q}^+$ , which is the **unique global minimum** of  $V_{b,a}$  in  $\mathcal{Q}^+$ .
- Setting  $h_c := V_{b,a}(x_c, y_c)$ , for  $h > h_c$  the level sets  $\{V_{b,a} = h\} \cap \mathcal{Q}^+$  are the **closed curves**.

$$C_h^+ := \{(bx+a)(ay+b)(ax+by+ab) - hxy = 0\} \cap \mathcal{Q}^+ \text{ for } h > h_c.$$

The dynamics of  $F_{b,a}$  restricted to  $C_h^+$  is *conjugate to a rotation* with associated *rotation number*  $\theta_{b,a}(h)$ .

## Theorem A

Consider the family  $F_{b,a}$  with  $a, b > 0$ .

- If  $(a, b) \neq (1, 1)$ , then  $\exists p_0(a, b) \in \mathbb{N}$  s.t. for any  $p > p_0(a, b)$ ,  $\exists$  at least an oval  $C_h^+$  filled by  $p$ -periodic orbits.
- The *set of periods* arising in the family  $\{F_{b,a}, a > 0, b > 0\}$  restricted to  $\mathcal{Q}^+$  contains *all prime periods except 2, 3, 4, 6, 10*.

## Corollary.

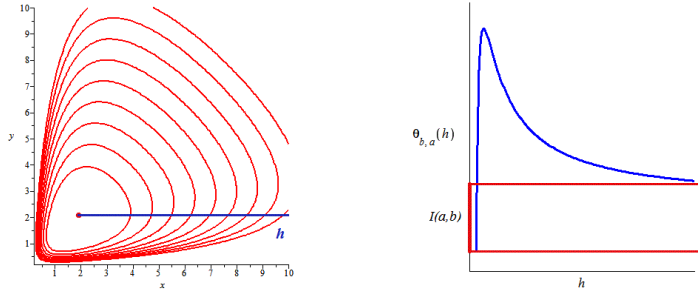

Consider the 2-periodic Lyness' recurrence for  $a, b > 0$  and positive initial conditions  $u_1$  and  $u_2$ .

- If  $(a, b) \neq (1, 1)$ , then  $\exists p_0(a, b) \in \mathbb{N}$ , s.t. for any  $p > p_0(a, b)$   $\exists$  continua of initial conditions giving  $2p$ -periodic sequences.
- The set of prime periods arising when  $(a, b) \in (0, \infty)^2$  and *positive initial conditions* are considered contains *all the even numbers except 4, 6, 8, 12, 20*.  
If  $a \neq b$ , then it does not appear any odd period, except 1.

The value  $p_0(a, b)$  is *computable* for an open and dense set in the parameter space.

To compute the allowed periods, the main issues to take into account are:

- The fact that the rotation number function  $\theta_{b,a}(h)$  is **continuous** in  $[h_c, +\infty)$ .
- The fact that **generically**  $\theta_{b,a}(h_c) \neq \lim_{h \rightarrow +\infty} \theta_{b,a}(h) \Rightarrow \exists I(a, b)$ , a **rotation interval**.

Proposition B.

$$\lim_{h \rightarrow h_c^+} \theta_{b,a}(h) = \sigma(a, b) := \frac{1}{2\pi} \arccos \left( \frac{1}{2} \left[ -2 + \frac{1}{x_c y_c} \right] \right), \quad \text{and} \quad \lim_{h \rightarrow +\infty} \theta_{b,a}(h) = \frac{2}{5}.$$

Corollary

$$\text{Set } I(a, b) := \left\langle \sigma(a, b), \frac{2}{5} \right\rangle.$$

- If  $\sigma(a, b) \neq 2/5 \forall \theta \in I(a, b)$ ,  $\exists$  an oval  $C_h^+$  s.t.  $F_{b,a}(C_h^+)$  is conjugate to a rotation, with a rotation number  $\theta_{b,a}(h) = \theta$ .
- In particular,  $\forall$  irreducible  $q/p \in I(a, b)$ ,  $\exists$  periodic orbits of  $F_{b,a}$  of prime period  $p$ .

The periods of the family  $F_{b,a}$ .

Using the previous results with the family  $a = b^2$  we found that:

$$\bigcup_{b>0} I(b^2, b) = \left( \frac{1}{3}, \frac{1}{2} \right) \subset \bigcup_{a>0, b>0} I(a, b) \subset \bigcup_{a>0, b>0} \text{Image}(\theta_{b,a}(h_c, +\infty)).$$

Proposition.

- For each  $\theta$  in  $(1/3, 1/2) \exists a, b > 0$  and an oval  $C_h^+$ , s.t.  $F_{b,a}(C_h^+)$  is conjugate to a rotation with rotation number  $\theta_{b,a}(h) = \theta$ .
- In particular,  $\forall$  irreducible  $q/p \in (1/3, 1/2)$ ,  $\exists p$ -periodic orbits of  $F_{b,a}$

We'll know some periods of  $\{F_{b,a}, a, b > 0\}$

$\Leftrightarrow$

We know which are the irreducible fractions in  $(1/3, 1/2)$

Lemma (Cima, Gasull, M; 2007)

Given  $(c, d)$ ; Let  $p_1 = 2, p_2 = 3, p_3, \dots, p_n, \dots$  be all the prime numbers.

- Let  $p_{m+1}$  be the smallest prime number satisfying that  $p_{m+1} > \max(3/(d-c), 2)$ ,
- Given any prime number  $p_n, 1 \leq n \leq m$ , let  $s_n$  be the smallest natural number such that  $p_n^{s_n} > 4/(d-c)$ .
- Set  $p_0 := p_1^{s_1-1} p_2^{s_2-1} \dots p_m^{s_m-1}$ .

Then, for any  $p > p_0 \exists$  an irreducible fraction  $q/p$  s.t.  $q/p \in (c, d)$ .

Proof of Theorem A (ii):

- We apply the above result to  $(1/3, 1/2)$ .  $\forall p \in \mathbb{N}$ , s.t.  $p > p_0$

$$p_0 := 2^4 \cdot 3^3 \cdot 5 \cdot 7 \cdot 11 \cdot 13 \cdot 17 = 12\,252\,240,$$

$\exists$  an irreducible fraction  $q/p \in (1/3, 1/2)$ .

- A finite checking determines which values of  $p \leq p_0$  s.t.  $q/p \in (1/3, 1/2)$ , resulting that there appear irreducible fractions with all the denominators except **2, 3, 4, 6 and 10**.
- Proposition C  $\implies \exists a, b > 0$  s.t.  $\exists$  an oval with rotation number  $\theta_{b,a}(h) = q/p$ , thus giving rise to  $p$ -periodic orbits of  $F_{b,a}$  for all allowed  $p$ .

- Still it must be proved that **2, 3, 4, 6 and 10** are forbidden, since

$$I(a, b) \subseteq \text{Image}(\theta_{b,a}(h_c, +\infty)) \quad \blacksquare$$

Continuity and asymptotic behavior of  $\theta_{b,a}(h)$ .

The curves  $C_h$ , in homogeneous coordinates  $[x : y : t] \in \mathbb{C}P^2$ , are

$$\tilde{C}_h = \{(bx + at)(ay + bt)(ax + by + abt) - hxyt = 0\}.$$

The points  $H = [1 : 0 : 0]$ ;  $V = [0 : 1 : 0]$ ;  $D = [b : -a : 0]$  are common to all curves

Proposition

If  $a > 0$  and  $b > 0$ , and for all  $h > h_c$ , the curves  $\tilde{C}_h$  are **elliptic**.

$F_{b,a}$  extends to  $\mathbb{C}P^2$  as  $\tilde{F}_{b,a}([x : y : t]) = [ayt + y^2 : at^2 + bxt + yt : xy]$ .

**Lemma.** Relation between the dynamics of  $F_{b,a}$  and the group structure of  $C_h$  (\*)

For each  $h$  s.t.  $\tilde{C}_h$  is elliptic,

$$\tilde{F}_{b,a|\tilde{C}_h}(P) = P + H$$

Where  $+$  is the addition of the group law of  $\tilde{C}_h$  taking the infinite point  $V$  as the zero element.

Observe that

$$F^n(P) = P + nH,$$

so  $\tilde{C}_h$  is full of  $p$ -periodic orbits  $\Leftrightarrow$

$$pH = V$$

i.e.  $H$  is a torsion point of  $\tilde{C}_h$ .

(\*) Birational maps preserving elliptic curves can be explained using its group structure (Jogia, Roberts, Vivaldi; 2006).

Instead of looking to a normal form for  $F$  we look for a normal form for  $\tilde{C}_h$ .

$$\begin{aligned} (\tilde{C}_h, +, V) &\cong (\hat{\mathcal{E}}_L, +, \hat{V}) \\ \tilde{F}_{|\tilde{C}_h} : P \mapsto P + H &\longrightarrow \hat{G}_{|\mathcal{E}_L} : P \mapsto P + \hat{H} \end{aligned}$$

Where  $\hat{\mathcal{E}}_L$  is the Weierstrass Normal Form which in the affine plane is:

$$\mathcal{E}_L = \{y^2 = 4x^3 - g_2x - g_3\}$$

with  $g_i := g_i(a, b, h)$ .

**WHY?**

- 1 Because we can parameterize it using the Weierstrass  $\wp$  function...
- 2 ...that gives an integral expression for the rotation number function.

$$2\Theta(L) = \frac{\int_{e_1}^{+\infty} \frac{ds}{\sqrt{4s^3 - g_2s - g_3}}}{\int_{e_1}^{+\infty} \frac{X(L) \sqrt{4s^3 - g_2s - g_3}}{ds}} \quad \text{where } \theta_{b,a}(h) \sim \Theta(L)$$

- 3 The asymptotics of this integral expression can be studied.

This scheme was used in (Bastien, Rogalski; 2004).

The Weierstrass normal form of  $C_h$  is

$$\mathcal{E}_L = \{y^2 = 4x^3 - g_2x - g_3\}$$

where

$$g_2 = \frac{1}{192} \left( L^8 + \sum_{i=4}^7 p_i(\alpha, \beta) L^i \right) \quad \text{and} \quad g_3 = \frac{1}{13824} \left( -L^{12} + \sum_{i=6}^{11} q_i(\alpha, \beta) L^i \right),$$

being

$$\begin{aligned} p_7(a, b) &= -4(\alpha + \beta + 1), \\ p_6(a, b) &= 2(3(\alpha - \beta)^2 + 2(\alpha + \beta) + 3), \\ p_5(a, b) &= -4(\alpha + \beta - 1)(\alpha^2 - 4\beta\alpha + \beta^2 - 1), \\ p_4(a, b) &= (\alpha + \beta - 1)^4. \end{aligned}$$

and

$$\begin{aligned} q_{11}(a, b) &= 6(\alpha + \beta + 1), \\ q_{10}(a, b) &= 3(-5\alpha^2 + 2\alpha\beta - 5\beta^2 - 6\alpha - 6\beta - 5) \\ q_9(a, b) &= 4(5\alpha^3 - 12\alpha^2\beta - 12\alpha\beta^2 + 5\beta^3 + 3\alpha^2 - 3\alpha\beta + 3\beta^2 + 3\alpha + 3\beta + 5) \\ q_8(a, b) &= 3(-5\alpha^4 + 16\alpha^3\beta - 30\alpha^2\beta^2 + 16\alpha\beta^3 - 5\beta^4 + 4\alpha^3 \\ &\quad - 12\alpha^2\beta - 12\alpha\beta^2 + 4\beta^3 + 2\alpha^2 - 8\alpha\beta + 2\beta^2 + 4\alpha + 4\beta - 5) \\ q_7(a, b) &= 6(\alpha^2 - 4\alpha\beta + \beta^2 - 1)(\alpha + \beta - 1)^3 \\ q_6(a, b) &= -(\alpha + \beta - 1)^6 \end{aligned}$$

where  $\alpha = a/b^2$  and  $b/a^2$  and  $L \rightarrow +\infty \Leftrightarrow h \rightarrow +\infty$ .

Since  $\hat{\mathcal{E}}_L \cong \mathbb{T}^2 = \mathbb{C}/\Lambda$ , the Weierstrass  $\wp$  function relative to a lattice  $\Lambda$  gives the parametrization of  $\hat{\mathcal{E}}_L$ .

$$\begin{aligned} \phi : \mathbb{T}^2 = \mathbb{C}/\Lambda &\longrightarrow \hat{\mathcal{E}}_L \\ z &\longrightarrow \left\{ \begin{aligned} &[\wp(z) : \wp'(z) : 1] \text{ if } z \notin \Lambda; \\ &[0 : 1 : 0] = \hat{V} \text{ if } z \in \Lambda, \end{aligned} \right. \end{aligned}$$

Hence  $\wp'(z)^2 = 4\wp(z)^3 - g_2\wp(z) - g_3$  since  $y^2 = 4x^3 - g_2x - g_3$ , and integrating on  $[0, u]$ :

$$(*) \quad u = \int_{\wp(u)}^{+\infty} \frac{ds}{\sqrt{4s^3 - g_2s - g_3}}$$

- $\hat{G}_{|\mathcal{E}_L}$  is a rotation with  $\Theta(L) \in [0, \frac{1}{2})$ , and  $\hat{G}_{|\mathcal{E}_L}(\hat{V}) = \hat{V} + \hat{H} = \hat{H}$
- $\hat{H}$  has negative ordinate  $\Rightarrow$  is given by  $u = 2\omega_1\Theta(L)$  and its abscissa is  $X(L) = \wp(2\omega_1\Theta(L))$ . Hence from (\*):

$$2\omega_1\Theta(L) = \int_{X(L)}^{+\infty} \frac{ds}{\sqrt{4s^3 - g_2s - g_3}} \quad \Rightarrow \quad 2\Theta(L) = \frac{\int_{e_1}^{+\infty} \frac{ds}{\sqrt{4s^3 - g_2s - g_3}}}{\int_{e_1}^{+\infty} \frac{X(L) \sqrt{4s^3 - g_2s - g_3}}{ds}} \sim \frac{4}{5}$$
